Chronic wasting disease (CWD) is a prion disease affecting cervid populations of North America. The ecology of the spread of the disease in Canada and the USA is closely related to changes in land use in combination with immunosuppressive management strategies, for which exposure of susceptible populations is enhanced. The incubation period is long, and thus the detection of CWD is challenging because of the long asymptomatic phase, which is sometimes preceded by clinical signs of other neurological diseases. The detection of CWD is facilitated by the development of highly specific molecular assays using quantitative real-time (QR) RT-PCR, which has become the standard method for the detection and quantification of CWD-positive brain samples. These assays require DNA amplification from an initial sample and include controls to verify amplification specificity and product integrity. Q-RT-PCR has also proven useful for the molecular detection of CWD-positive excreta and saliva. In this review we describe the origin and spread of CWD and the molecular methods used to identify and quantify the agent. Lastly, we discuss measures to control CWD in human and animal populations. form=0& tags= Bifocal Point-of-Care Ultrasound. Ultr 6d1f23a050
